3. Board member, Scotland College of Chiropractic Trust

ABSTRACT

Objectives: To present the case of a 7-year-old female previously diagnosed with Attention-Deficit Hyperactivity Disorder (ADHD), and the improvement and management of symptoms under regular chiropractic care, including the integration of a retained asymmetrical tonic neck reflex (ATNR). Methods: Online review of the literature on motor development delay and chiropractic was performed using The Index to Chiropractic Literature, PubMed and Google Scholar. Search terms “ADHD”, “chiropractic” and “spinal manipulation” were used. Clinical features: A 7-year-old female previously diagnosed with ADHD presented with anxiety, sleep disturbances, learning difficulties and behavioral issues. Her mother reported sleep disturbances began at 22-months following a fall onto her forehead. Previous treatments for ADHD, including behavioral therapy, psychotherapy and dietary intervention, had marginal success. A retained ATNR and aberrant H-test (cranial nerves III, IV, and VI) was identified. Direct objective indicators of vertebral subluxation at C1, T2, T4, T9, and sacrum were identified on spinal examination. Intervention and outcomes: Modified Diversified using an Activator instrument as a force application was applied to correct vertebral subluxation. Within the 4 visits, the child’s behavior, mood and sleep patterns had improved, and the retained ATNR had integrated. Cranial nerve findings had resolved. Direct objective indicators of vertebral subluxation had reduced. Ongoing care continued to improve and manage the presenting behavioral symptoms. Conclusion: Chiropractic care focused on the correction of vertebral subluxation, was associated with improvements in the child’s presenting symptoms associated with ADHD.

Key words: Attention Deficit Hyperactivity Disorder; ADHD; Chiropractic; Pediatric; Vertebral Subluxation; Chiropractic Spinal Manipulation.

Introduction

Attention Deficit Hyperactivity Disorder (ADHD) is a complex pattern of persistent inattention and/or hyperactivity and impulsiveness that can interfere normal functioning or development.¹-³ Within the criteria, an individual’s academic and/or occupational activities are assessed relative to the expected developmental level of that individual’s age.¹-³ The inattentive and/or hyperactive-impulsive symptoms must have a detrimental effect on the quality of social, academic or occupational functioning.³

ADHD is considered to be common behavioral disorders in children and adolescents.²,⁴,⁵ It has been estimated, through the Global Burden of Disease study, that 26 million children and adolescents have ADHD.³ Over the past two decades there has been a significant increase in the prescription of medications for children diagnosed with ADHD.⁶-⁸ Ritalin and Dexamphetamine are stimulants that have been used for over 40 years with short-term success in managing the symptoms of ADHD in 80-90% of children.⁹ The steady increase in diagnoses of ADHD in the past decade is only compounded by the concern that current best practice for treatment (pharmaceutical intervention) does not actually treat the cause of ADHD, it only haphazardly manages the symptoms.⁹

Current non-pharmaceutical treatments for ADHD, including behavioral therapies,¹⁰ educational therapies,¹¹ family counselling,¹² and dietary or nutritional intervention,¹³,¹⁴ have exhibited varying degrees of success, though none stand out as significantly more effective than others. A common approach is to combine these methods to have a cumulative effect.¹⁵

Chiropractic care for the pediatric population has grown in acceptance.¹⁶,¹⁷ Parents regularly choose chiropractic care to help manage common childhood conditions.¹⁸,¹⁹ Chiropractic care aims to optimize health and wellbeing through the enhancement of the nervous system function by removing nerve interference caused by vertebral subluxation.²⁰ A vertebral subluxation represents an altered state of afferent input which can lead to maladaptive changes in central neural plasticity resulting in dysfunction.²⁰ The Australian Spinal Research Foundation developed a conceptual definition of vertebral subluxation that states, “A vertebral subluxation is a diminished state of being, comprising of a state of reduced
coherence, altered biomechanical function, altered neurological function and altered adaptability.\textsuperscript{21} The correction of vertebral subluxations is achieved through chiropractic adjustments that are typically manually performed.\textsuperscript{22-24}

Current literature regarding the chiropractic management of pediatric patients with ADHD is limited, and primarily of a low level of evidence.\textsuperscript{25-27} The evidence to date suggests that chiropractic care may be beneficial for this population.\textsuperscript{27} The purpose of this study is to report the improvements in symptoms associated with ADHD in a 7-year-old female following chiropractic care.

**Methods**

To assess the relevance to chiropractic, an online review of the literature on ADHD and chiropractic was performed. The Index to Chiropractic Literature and PubMed were consulted using the search terms “ADHD,” “chiropractic” and “spinal manipulation.” Databases were searched from inception through July 2017, with peer-reviewed and complete systematic reviews, clinical trials, case series and case reports, all being included. Abstracts from research symposia were not included in the review.

**Case Report**

**History**

A 7-year old female with anxiety, sleep disturbances, learning difficulties and behavioral issues presented for chiropractic assessment. The presenting complaints were reported to be worsened by overstimulation and change of routine.

A review of the child’s health history revealed a birth requiring forceps and ventouse extraction. The child’s sleep disturbances are reported to have begun at 22-months of age, following a minor fall resulting in a laceration above her nose requiring medical management to suture the wound. Her sleep disturbance is reported as lacking the ability to fall asleep.

The child’s anxiety is reported to be associated with being bullied at school. Her learning difficulties and behavioral issues are reported as a greatly reduced attention span, and difficulty in following instructions at home and at school. She was medically diagnosed at age seven with ADHD by a general practitioner and pediatrician. It is unknown if the general practitioner or pediatrician used a formal instrument to assess ADHD. The pediatrician prescribed Ritalin, however the child’s parents were interested in seeking alternative solutions.

Previous treatments sought include cognitive behavioral therapy (CBT), psychotherapy and dietary changes. The parents reported these to be ineffective in helping manage their daughter.

**Examination**

The child presented with an unsettled demeanor and short attention span, was distracted, hyperactive and had difficulty following instructions. Generally, the child’s gait and coordination were observed to be normal.

Postural analysis revealed a high left mastoid and shoulder with left scapular winging. Anterior tilt of the pelvis was also noted. No other postural abnormalities were reported. All global ranges of motion were within normal limits. Posture and ranges of motion were assessed via manual observation and palpation only.

Neurological examination presented with a retained bilateral asymmetrical tonic neck reflex (ATNR).\textsuperscript{28} Assessment of cranial nerves III, IV, and VI revealed inability to track on H-test (by having the patient follow an object moved across their full range of horizontal and vertical eye movements by the chiropractor), especially the right eye, with saccadic pursuit at the lateral right of H-test.\textsuperscript{29}

Initial chiropractic examination for vertebral subluxation was performed using commonly used clinical indicators.\textsuperscript{30-35} Direct objective indicators of vertebral subluxation at C1, T2, T4, T9 and sacrum were identified through static and motion palpation, leg length inequality, Derifield assessment, sacral restriction test and cervical syndrome test.

**Intervention**

Informed consent was obtained from the child’s mother at the initial consultation for the child to begin chiropractic care. Full spine chiropractic care was administered over a period of 11-weeks at a frequency of one visit per week. Vertebral subluxations were routinely assessed using static and motion palpation, muscle testing, muscle palpation and leg length analyses including leg length inequality, Derifield, cervical syndrome and sacral restriction.\textsuperscript{30-35}

Chiropractic adjustments were made using Diversified technique (Activator™ instrument assisted). Diversified is the most widely used chiropractic technique and system of adjusting that uses primarily motion and static palpation to locate levels of vertebral subluxation, and focuses on the restoration of proper biomechanics within the spine.\textsuperscript{36} The most commonly adjusted levels of the child’s spine were C1, the left sacrum and T9, addressed 10, 9 and 8 out of the 11 visits respectively. For a detailed list of spinal levels addressed each visit see Table 1.

When the child began chiropractic care, she was seeing a counsellor weekly for CBT. She had undergone three visits...
for CBT prior to commencing chiropractic care. Only two further visits were attended once starting chiropractic care as the child’s change in behavior was rapid, and the mother did not believe CBT had been as effective.

Outcomes
Over the course of chiropractic care the child demonstrated reduction in symptoms associated with ADHD, was less anxious and had improved sleep patterns. Following the second visit the parents reported that the child’s sleep patterns had improved markedly, and had noticed improvement in her behavior and anxiety levels. By the third visit the parents reported she was able to better concentrate. At the time of the fourth visit the child had had a successful sleepover for the first time, and clinical examination revealed resolution of ATNR.

Generally, the child’s behavior was reported to have improved over the course of care and now remains under the chiropractor’s care at a reduced visit frequency, every two to three weeks as recommended each visit, for regular wellness care. For a detailed list of reported and observed changes in the child’s behavior and presenting complaints see Table 1. No adverse reactions were identified or reported during the course of chiropractic care.

Cranial Nerve examination (CN III, IV, and VI) revealed normalization of ocular tracking on H-test. Saccadic pursuit on lateral right H-gaze had resolved.

Chiropractic spinal examination revealed a right leg length inequality and negative Derifield (short leg remaining short on knee flexion to 90°), right Levator Scapula hypertonicity, right C5/6 edema, and decreased joint play and intersegmental motion of T3/4. These findings indicated a reduction of direct objective indicators of vertebral subluxation when compared to the initial presentation of the patient.

Discussion
Improvements in behavior associated with ADHD, sleep patterns and anxiety were reported in a 7-year-old female over the course of 11-weeks of chiropractic care. The child had a 5-year history of sleep disturbance, anxiety associated with school bullying, and ADHD medically diagnosed at age seven prior to commencing chiropractic care.

Most commonly a pharmaceutical approach is used in the treatment of ADHD, however there has been concern about this approach.6-9 Non-pharmacological approaches such as dietary change and counselling have shown some positive benefits, and more so when used in combination.10-15 Com-

Improvement in behavior and attention in a 7-year-old girl with ADHD receiving chiropractic care: A case report and literature review

Plummary and alternative medicine (CAM) approaches are used by parents and healthcare providers, with ADHD being one of the most common reasons for seeking care.29 Chiropractic care is one of the more common CAM modalities that parents choose for children, though still a very niche area.37 Therefore, it is important to investigate the effect of chiropractic care on a child with ADHD.

While the chiropractic literature for this specific population is limited, a literature review revealed three systematic reviews of the literature,25–27 one clinical trial,15 one qualitative study,38 four case series39–42 and 18 case reports43–60 relevant to chiropractic management of people presenting with ADHD. All but one study described the care of pediatric patients. The clinical trial only described the proposed protocol for the study, results were to be published at a later date.15

The systematic reviews all report that the literature regarding the chiropractic management of pediatric patients with ADHD is not only limited, but primarily of a low level of evidence.25–27 The most recent systematic review however does suggest that chiropractic care may be beneficial for this population, though recognizes that higher level investigation is necessary.25

Hermansen and Miller38 conducted a qualitative study that adds weight to the inclusion of a biopsychosocial model in the clinical management of people with ADHD. In the study chiropractic care was well received by the patients reported by high levels of satisfaction, two-thirds of the study chiropractic care was well received by the patients in the clinical management of people with ADHD. In the study, results were to be published at a later date.15

The case reports suggest a generally positive benefit of chiropractic care with children and adolescents who present with ADHD.33–60 For a review of the case reports see Table 2.

Of the 23 peer-reviewed studies (qualitative study, and case series and reports) describing chiropractic management of patients presenting with ADHD, 15 (65.21%) specifically reported assessment and correction of vertebral subluxation,41,44,46–55,57,58 with 17 (73.91%) describing direct clinical indicators commonly used in the assessment of vertebral subluxation.41,44,46–55,57,58,60 The most commonly used approaches to address vertebral subluxation were Upper Cervical and Diversified techniques.39,40,43–45,49,52,54,55,59 Ten (43.47%) of the 23 studies reported additional intervention, such as auriculotherapy, soft tissue therapy and dietary supplementation in conjunction with chiropractic care.39,45,47,51,54,56,59

Seventeen (73.91%) of the 23 studies describe formal/medicall diagnosis of ADHD.38–45,47–50,53,55,57,59 One further case was assessed through the schooling system.51 Improvements in symptoms associated with ADHD were self-reported in the majority of cases, thought there is little evidence of improvement following a course of chiropractic care being measured via a formal assessment instrument such as the TOVA test.39,41–45 In three cases a medical practitioner or therapist determined that the symptoms associated with ADHD had improved or resolved, though it is unclear if a formal assessment was used.50,57,59 In many cases the published literature indicates that reported improvements are either from parent and/or teacher observations, or self-reported.36,40,40–45,51–56,58,60

Though limited, the current literature suggests that chiropractic care can improve symptoms related to ADHD.27,38–41,43–47,49–58 The findings from the current case study is congruent with previously reported studies investigating the effects of chiropractic care on the symptoms associated with ADHD. Of note is that the majority of studies report the assessment and correction of vertebral subluxation being associated with improvements, giving weight to research that investigates the vertebral subluxation in general.61,62 This study supports the use of chiropractic care for children and

Pauli26 reported on nine adults (four male and five female) presenting with ADHD assessed via the TOVA test. Chiropractic care using Network Spinal Analysis over a two month period resulting in all patients demonstrating significant improvements on the TOVA test.

Cuthbert and Barras40 reported on 157 children (86 male and 71 female) aged 6 to 13 diagnosed with developmental delay syndromes, including ADHD, via psychometric testing by a logopedist. Chiropractic care using Applied Kinesiology and Diversified techniques for 2 to 50 visits over a period of 5-days to 18-months. Parents reported behavioral improvements in all cases.

Hodgson and Vaden40 reported on four children aged eight to 12 who had been formally diagnosed with ADHD us-
young adults with ADHD.

**Limitations**

There are inherent limitations of a single case study. These include lack of a control group, and the inability to exclude spontaneous remission, accounting for cumulative effects of previous care, or a self-limiting clinical presentation. We caution the reader that generalizations to a larger population cannot be made. In this case the assessment of ADHD was made through a medical practitioner assessment but may not have been via an instrument such as a TOVA test. Reported improvements were through subjective observations made by the parents and chiropractor. Additionally, there were limited outcome measures used in the management of this child.

A further limitation is the current lack of higher level investigation into the chiropractic care of this population. Further higher level investigation should be undertaken by the profession.

**Conclusion**

Chiropractic care, using instrument assisted Modified Diversified technique for the correction of vertebral subluxation, was associated with improvements in the child’s presenting symptoms associated with ADHD. Higher level research is needed to investigate the role chiropractic may play in helping infants and children who present with ADHD.

Improvement in behavior and attention in a 7-year-old girl with ADHD receiving chiropractic care: A case report and literature review

| Olafsson53 | 4 ½ year old male with suspected ADHD but not formally diagnosed | 10 visits over 10 weeks, with dietary changes and exercises being prescribed. Diversified technique | Parent reported behavioral changes |
| Cassista54 | 4-year-old male with sleep disturbances and ADHD diagnosed by a pediatrician | 3 visits per week for 2 ½ months, then reduced frequency to periodic care due to parents moving away. Pettibon technique | Parent reported behavior changes. The child’s behavior reverted to pre care behavior and when assessed again after a 16 month hiatus from care the child demonstrated a marked increase in VS indicators similar to pre care |
| Stone-McCoy and Przybysz55 | 3 ½ year old male diagnosed with ADHD by a psychologist | 3 visits weekly for 3 weeks, 1 visit weekly for 8 weeks, 1 visit every other week. Omegas and proprioceptive exercises were also introduced. Upper cervical technique | Parent and teacher reported improved behavior (attention and energy levels) |
| Elster56 | 9-year-old male with respiratory issues, ADHD, depression, insomnia and headaches. ADHD was diagnosed by a neurologist via the Attention Deficit profile worksheet | 5 months Upper cervical technique | Parent, practitioner and self-reported improved behavior |
| Blum and Cuthbert57 | 2-year-old female with delayed developmental and emotional growth. | 5 years Craniocervical therapy. (multi mineral supplement also given) | Parent reported changes in behavior. At 7 years of age is equal to her twin brother |
| Bastecki et al.58 | 5-year-old male with ADHD unsuccessfully treated with Ritalin. ADHD was medically diagnosed via the common ADHD checklist | 35 visits over 8 weeks Chiropractic Biophysics technique | Medical doctor determined child no longer exhibited ADHD symptoms |
| Jaszewski and Sorbara59 | 7-year-old female with ADD, difficulty concentrating, vomiting and migraine. ADD was not formally diagnosed | 1 visit weekly for 5 weeks Pierce Results System technique | Parent reported changes in behavior |
| Young60 | 4-year-old male with multiple behavioral conditions. ADHD was medically diagnosed | 12 weeks (6 visits) with proprioceptive exercises, and dietary changes and supplements prescribed. Upper cervical technique | Parents, teachers and speech therapist reported positive behavior changes |
| Lovett and Blum61 | 8-year-old male with behavioral symptoms associated with ADHD but not formally diagnosed | 8 weeks (weekly visits) Sacro-Occipital Technique | Parents and teacher reported improvement in behavior |
